Universitaria, Copilco Coyoacán, A. P. 70-233, C. P. 04510., D. F., México; azaldivar@ibiologia.unam.mx

**Abstract.**—A new species of *Neoheterospilus*, *N. chamelae* n. sp., is described from the Chamela-Cuixmala biosphere reserve in the Pacific coast of Jalisco, Mexico. This new species is placed within the subgenus *Harpoheterospilus* as it has an almost indistinct suture between the second and third metasomal terga and by the absence of a delineated apical area on the second metasomal tergite. *Neoheterospilus chamelae* is distinguished from the other species of the subgenus, *N. (H.) falcatus*, by its smooth vertex, single transverse carina in the prescutellar sulcus, a longer basal carina on the propodeum, and an elongate first metasomal tergite.

**Resumen.**—Se describe una nueva especie de *Neoheterospilus*, *N. chamelae* n. sp., de la reserva de la biosfera Chamela-Cuixmala en la costa del Pacífico en Jalisco, México. Esta nueva especie es incluida dentro del subgénero *Harpoheterospilus* por tener una sutura casi indistinguible entre el segundo y tercer tergos metasomales, y por la ausencia de un área apical delineada en el segundo tergo metasomal. *Neoheterospilus chamelae* se distingue de la otra especie del subgénero, *N. (H.) falcatus*, por presentar un vertex liso, una sola carina transversal en el surco prescutelar, y la carina basal en el propodeo y el primer tergo metasomal más largos.

The doryctine genus *Neoheterospilus* was erected by Belokobylskij (2006) to contain ten species, three of which were previously described and assigned to the megadiverse, polyphagous genus *Heterospilus* Haliday. *Neoheterospilus* was distinguished from the latter genus on the basis of a highly modified, unusually shaped ovipositor, and on the frequent presence of a basal area on the second metasomal tergite. This author also placed the genus in the tribe Heterospilini and divided it into two subgenera: *Neoheterospilus*, represented by nine species from the South Palaearctic and Old World tropics, and *Harpoheterospilus*, which included only one species, *N. falcatus* (Marsh), originally described from Venezuela and Brazil (Quicke and Marsh 1992). Recent collecting trips carried out as part of an ongoing barcoding study of the doryctine fauna from the Chamela-Cuixmala Biosphere Reserve, in Jalisco, Mexico, have revealed the existence of an undescribed species of *Neoheterospilus*. Here we describe this new species, which represents the first record of the genus in Mexico and Mesoamerica. Preliminary molecular evidence has shown that *Neoheterospilus* may represent a derived lineage within *Heterospilus* (Zaldívar-Riverón et al., in prep.). However, we maintain the current status of this taxon until more evidence is gathered.

**MATERIALS AND METHODS**

Specimens assigned to *Neoheterospilus* were collected during three field trips to...
the Chamela-Cuixmala Biosphere reserve carried out during June, September and November 2009, and February 2010. Four different collecting techniques were employed during these trips, though all specimens of the new species were collected either with light traps or sweep nets. All specimens were preserved in 100% ethanol and subsequently taken to the laboratory to obtain DNA sequence data for a barcoding study using a non-destructive DNA extraction technique. All specimens were air dried and mounted. Specimens are deposited in the Colección Nacional de Insectos (CNIN), Instituto de Biología, Universidad Nacional Autónoma de México, and in the Museo Argentino de Ciencias Naturales "Bernardino Rivadavia", Buenos Aires, Argentina (MACN).

Association of males with the newly described species was confirmed by generating barcoding sequences for all specimens of both sexes. Sequence data for the specimens included in this study will be published elsewhere. Our description mostly follows Belokobylskij's (2006) format in order to facilitate comparison of the new species with the described species of the genus. The terminology employed follows Sharkey and Wharton (1997), but Belokobylskij and Maeto's (2009) wing venation nomenclature is also included in parentheses. Photographs were taken and edited using a Leica® Z16 APO-A stereoscopic microscope, a Leica® DFC295/DFC290 HD camera, and the Leica Application Suite® program. All photographs were uploaded to the Morphbank web site (www.morphbank.org).

**TAXONOMY**

**Neoheterospilus (Harpoheterospilus) chamela n. sp.**

*(Figs 1A–F, 2A–D)*

**Description.—Female:** Body length 2.6–3.5 mm (Fig. 1A); fore wing length 2.0–2.4 mm.

**Head:** 1.6–2.0 times wider than median length. Occipital carina complete and joining hypostomal carina before mandible. Head behind eyes (dorsal view) roundly narrowed. Transverse diameter of eye 2.4–2.6 longer than temple (dorsal view). POL 0.7–1.0 times Od, 0.5–0.7 times OOL. Eye 1.2–1.3 times as high as broad. Malar space 0.2–0.3 times eye height, 0.6–0.8 times basal width of mandible. Face
Fig. 1. *Neoheterospilus chamelae* n. sp.: A, habitus of female, lateral view; B, head, anterior view; C, head, lateral view; D, head, dorsal view; E, mesosoma, lateral view; F, mesosoma, dorsal view.

Width 1.5–1.6 time eye height of face and clypeus combined. Width of hypoclypeal depression 1.6–1.8 times distance from edge of depression to eye, 0.3–0.4 times width of face. Antenna filiform, 24–25 antennomeres. Scapus 1.3–1.4 times as long as maximum width. First flagellomere 4.0–4.5 times longer than wide, 1.1–1.2 longer than second segment. Penultimate flagellomere 0.4–0.5 times as long as wide, 0.6 times as long as first segment, as long as apical flagellomere.

**Mesosoma** (Figs 1E, F): 1.7–1.8 times longer than high, and 1.8–1.9 times longer than wide. Mesoscutum 0.7–0.8 times as long as wide. Median lobe of mesoscutum weakly convex anteriorly. Prescutellar depression with a single median carina, finely
rugulose, 0.4–0.5 times as long as scutellum. Sternauli wide and scrobiculate.

Wings: fore wing 3.0–3.3 times longer than wide (Fig. 2D). Pterostigma 0.7–0.8 times as long as R (metacarpus). Vein r (first radial abscissa) 1.3–1.7 times as long as 3Rs (second radial abscissa), 0.3 times as long as 3Rs (third radial abscissa), and 0.5–0.6 times as long as trace of 2Rs (first radiomedial vein). Vein (RS+M)a (first abscissa of medial vein) slightly curved. Discal (discoidal) cell 1.4–1.7 times longer than wide. Hind wing 5.0–5.2 times longer than wide. Vein SC+R (second abscissa of costal vein) absent. Vein M+CU (first abscissa of mediocubital vein) 0.7–0.8 times as long as 1M (second abscissa). Vein m-cu (recurrent vein) unsclerotised.

Metasoma: 1.1–1.2 times as long as head and mesosoma combined (Fig. 2A). First tergite slightly widened towards apex, 1.7–2.1 times longer than apical width; its basal sternal plate (acrosternite) 0.3 times as long as first tergite. Basal area of second tergite absent. Median length of second tergite 0.7–0.9 times its basal width, 1.1–1.3 times length of third tergite. Second suture shallow, almost indistinct. Ovipositor sheath 0.8–1.0 times as long as metasoma. Ovipositor thick, its apex sickle shaped (Fig. 2C). Ovipositor sheath distinctly and irregularly widened apically.

Sculpture and pubescence: Vertex smooth, occasionally with faint and poorly defined transversal striate sculpture (Fig. 1D); frons smooth (Figs 1B, D); face weakly acinose-coriaceous, turning smooth and slightly swollen medially (Fig. 1B); temple smooth (Fig. 1C). Pronotum coriaceous (Fig. 1E), pronotal furrow distinctly scrobiculate, mesoscutum strongly coriaceous, with rugose medioposterior area;
notauli complete and scrobiculate; scutellum coriaceous; prescutellar depression smooth to finely coriaceous, with a single median carina (Fig. 1F). Mesopleuron smooth medially, turning coriaceous posteriorly; subalar groove scrobiculate; sternaulus deep and scrobiculate (Fig. 1E). Metapleuron coriaceous, with two subvertical carinae posteriorly. Basolateral areas of propodeum coriaceous; remaining areas of propodeum strongly rugose-reticulate; areola delineated by carinae, with long median carina, 0.7–0.8 times as long as median length of scutellum (Fig. 1F). Hind coxa entirely coriaceous. Hind femur slightly coriaceous, turning smooth ventrally. First metasomal tergite longitudinally striate, with two more distinct anterior longitudinal carinae along anterior half of tergite; second tergite longitudinally striate, occasionally with weak granular sculpture between striae; remaining terga smooth (Fig. 2A). Head except eyes, mesoscutum, and pronotum covered by short, erect setae. Mesopleuron glabrous medially. Propodeum and metapleuron sparsely setose. Hind tibia with short semi-erect setae, more dense ventrally. Metasoma with first and second terga with sparsely and uniformly distributed short setae, remaining terga mostly glabrous, only with a transverse row of sparse setae subapically. Ovipositor sheath uniformly covered by long, erected setae.

**Colour:** Head, mesosoma and metasoma honey yellow (Fig. 1A); antennae honey yellow basally, gradually turning brown to the tip; ventral side of head, mouth parts, legs and ventral surface of metasoma pale yellow. Ovipositor sheath dark brown. Wings hyaline, veins light brown, pterostigma brown (Fig. 2D).

**Male.—**Body length 1.7–2.3 mm. Fore wing length 1.4–1.9 mm. Hind wing with brown to honey yellow sclerotised enlargement, length almost equal to distance from base of hind wing to base of enlargement. Similar to female except darker metasomal terga, with second and apical part of first tergites pale yellow. Second tergite entirely and third in basal half striate. Antenna with 17–22 antennomeres. First metasomal tergite 1.5–1.7 times longer than apical width.

**Remarks.—**This species is similar to *N. (H.) falcatus*; however, it differs by having the body honey yellow (brown in *N. falcatus*; Fig. 3A), vertex usually smooth (coriaceous in *N. falcatus*; Fig. 3B), a single transverse carina in the prescutellar sulcus (three to five in *N. falcatus*; Fig. 3C), a longer basal carina on the propodeum (less than 0.7 times as long as median length of
scutellum in *N. falcatus*), and by an elongate first metasomal tergite (1.7–2.0 times longer than wide; 1.3–1.5 times in *N. falcatus*).

*Neoheterospilus chamelae* is included in the subgenus *Harpoheterospilus* by the almost indistinct suture between the second and third metasomal terga and the absence of a delineated apical area on second metasomal tergite. However, it differs from the original concept of the subgenus by having a single median carina in the prescutellar depression, and by usually having a smooth vertex.

**ACKNOWLEDGMENTS**

We thank Robert Kula (USNM) for the loan of type specimens of *N. falcatus*; Susana Guzmán-Gómez (UNIBIO, Instituto de Biología, UNAM) and Vladimir de Jesús-Bonilla for helping with the microscope digital images; Andrés Reséndiz-Flores, Ma. Cristina Mayorga-Martínez, and Guillermina Ortega-León for mounting the type specimens; and Hans Clebsch for his invaluable assistance during the collecting trips. This study was supported by a grant given by the Comisión Nacional para el Conocimiento y Uso de la Biodiversidad (CONABIO, México) to AZR, and by a short term fellowship given by Comisión Nacional de Investigaciones Científicas y Técnicas (CONICET, Argentina) to JJM.
