Resumen:

The objective of the proposal is to model the geographic distribution of *Pinus pseudostrobus* and *P. leiophylla*, by predicting the distribution of their suitable habitat from climate variables. Both species are very important on their ecological role as components of the pine-oak and coniferous forest in México. *Pinus pseudostrobus* is one of the most economically important species in the Neovolcanic Axis (named also Trans-Mexican Volcanic Belt) for its good wood quality, relatively fast growth rate and straight stem. *P. leiophylla* is usually heavily tapped for resin production and its distribution reaches southern USA, making it a subject for bi-national interest due to its potential to colonize USA grassland-forest transition areas under climatic change scenarios. We will use presence/absence data from (a previously screened for errors) Mexican National Forest Inventory and climatic variables estimated by a spline climate model. Presence or absence in the contemporary climate will be predicted from climate variables obtained for each observation from spline climate surfaces available for Mexico and the rest of North America. A climate profile for each species will be constructed by selecting 5 to 8 of the most relevant climatic variables from 36 climatic variables using the Random Forests algorithm in R. Relevant climate variables are selected according to importance values calculated by the statistical software and according to the errors of prediction of the classification tree. The best fitting models will be used to predict the suitability of the climate for the species on maps gridded at 1 km², and distribution maps will be constructed with ArcMap. As an extra product, we will predict the distribution of their suitable habitat for the years 2030, 2060 and 2090, using combinations of three General Circulation Models and two emission scenarios (low and elevated emissions). We considered that management plans for both biological conservation and commercial use must consider actions to accommodate the climatic change, such as assisted migration or assisted colonization.

Abstract

The objective of the project was to model the geographic distribution of *Pinus pseudostrabus* and *P. leiophylla*, by predicting the distribution of their suitable habitat from climate variables. Both species are very important on their ecological role as components of the pine-oak and coniferous forest in Mexico. *Pinus pseudostrabus* is one of the most economically important species in the Neovolcanic Axis (named also Trans-Mexican Volcanic Belt) for its good wood quality, relatively fast growth rate and straight stem. *P. leiophylla* has an extensive distribution along the interior slopes of Sierra Madre Occidental, and is usually heavily tapped for resin production. We used presence/absence data from (a previously screened for errors) Mexican National Forest Inventory and climatic variables for contemporary climate (average 1961-1990), that were estimated by a spline climate model. A climate profile for each species was constructed by selecting the most six relevant climatic variables for *P. leiophylla* and seven for *P. pseudostrabus*, from 36 climatic variables using the Random Forests algorithm in R. The bioclimatic models had an average error of prediction of 4.6 % for *P. leiophylla*, and 5.7 % for *P. pseudostrabus*. The selected models were used to predict the suitability of the climate for the species on maps gridded at 1 km², and distribution maps were constructed with ArcMap. The predicted area represented well the actual distribution of both species, were nearly all the presence sites were superimposed by the predicted area when probability of the suitable climatic habitat was > 0.5.

Introduction

Biogeographers view climate as the primary factor controlling the distribution of plants (Tukanen 1980; Brown and Gibson 1983; Woodward 1987). Then, modeling the relationship between presence and absence of a species from climatic variables at the sites of occurrence or absence makes it possible to predict the geographic distribution of climatically suitable habitats for a species, that is, the realized climatic niche. On this project we predicted the occurrence of climatically suitable habitats for two conifers with a model built on the framework of Iverson et al (2008) that closely parallels those of Rehfeldt et al. (2006).

The approach uses the Random Forests classification tree (Breiman, 2001), available in R (R Development Core Team 2004; Liaw and Wiener 2002), to predict the presence–absence of a species from climate variables. The procedure has been employed to model contemporary and future distributions of the climatic niche for Mexican endemic rare species, *Pinus chiapensis* (Sáenz-Romero et al 2010); *Picea chihuahuensis*, *P. mexicana* and *P. martinezii* (Ledig et al 2010); the high altitude *Abies religiosa* (Sáenz-Romero et al 2012) and *Pinus leiophylla* on their portion of USA distribution (Rehfeldt et al 2006). Compared to other techniques for modeling presence-absence, the Random Forests classification tree is superior when the database contains a broad representation of observations for both presence and absence. We have made our predictions with a very low “out-of-bag” errors: 4.7 % for *P. chiapensis* (Sáenz-Romero et al 2010), 4.5 % for the three *Picea* (Ledig et al 2010), and 1.85 % for *A. religiosa* (Sáenz-Romero et al 2012).

The quality of the prediction is also related to the reliability of the input data. We have solved the need of precise information of climate variables by constructing a spline climatic model for México (Sáenz-Romero et al 2010) and for all North America (Rehfeldt 2006; Rehfeldt et al 2012). Climate estimates from the climate model can be obtained from a web site (Crookston and Rehfeldt 2011). We used distribution data from the Mexican National Forest Inventory. However, an important asset is the knowledge of the species ecological relationships that were acquired by the last author during botanical collections for many years and by the senior author during years of collaboration with the Native Indian Community of Nuevo San Juan Parangaricutiro, Michoacán, where both species

occur. In addition, several seed collections and field testing has been conducted for *P. pseudostrobus* (Viveros-Viveros et al 2005, 2006, 2007; Sáenz-Romero et al 2011) and for *P. leiophylla* (Castellanos-Acuña et al 2012).

Pinus pseudostrobus and *P. leiophylla* both have important ecological roles as primary components of the pine-oak and coniferous forests of several mountain ranges in México, playing the role of key-stone species when dominant or codominant, providing structure, shade and support to many other species, and organic material to form soils (Perry, 1991; Farjon and Styles 1997; López-Upton, 2002; Musálem y Martínez-García, 2003).

Pinus pseudostrobus distributes in the Neovolcanic Axis (named also Trans-Mexican Volcanic Belt), Sierra Madre Oriental, Sierra Norte de Oaxaca, Altos of Chiapas and of Guatemala (Madrigal-Sánchez 1982; Perry, 1991; Farjon and Styles 1997; López-Upton, 2002). *Pinus leiophylla* distributes in the Neovolcanic Axis, Sierra Madre Occidental (up to southern Arizona and Nuevo México, USA), Sierra Norte de Oaxaca and Altos of Chiapas (Perry, 1991; Farjon and Styles 1997; Musálem y Martínez-García, 2003; Rehfeldt et al 2006).

Additionally to their ecological importance, *Pinus pseudostrobus* is one of the most economically important species in the Neovolcanic Axis for its relatively fast growth rate, natural self-pruning and straight stem, making it one of the most important species for timber production and a promising species for intensive commercial plantations (López-Upton, 2002). *P. leiophylla* is usually heavily tapped for resin production in México, particularly in Michoacán state (Musálem y Martínez-García, 2003) and its distribution reaches southern USA (Rehfeldt et al 2006).

Objective

To model the geographic distribution of the suitable climatic habitat for *Pinus pseudostrobus* and *P. leiophylla*, primarily for México.

Methodology

Pinus leiophylla

Considerations about presence data input

We constructed our database of presence observations mainly from field presence observations of *P. leiophylla* (both 766 observations of *P. leiophylla* var. *leiophylla* and 752 observations of putative *P. leiophylla* var. *chihuahuana*), from a subset of 6674 observations with presence of conifers from the Mexican National Forest and Soil Inventory (MexFI), elaborated by the Mexican National Forest Commission (Comisión Nacional Forestal, CONAFOR). Observations were provided from the latest data base version on January 2010, that encompassed field observations from 2004 to 2009 (Vargas-Llamas and Palafox-Rivas, pers. com.¹, 2012). Mexican Inventory customarily establishes plots with four subplots which were combined for our analysis.

We considered *P. leiophylla* Schiede ex Schlechtendal & Chamisso as a single species, lumping together putative varieties *P. leiophylla* var. *leiophylla* Schiede ex Schlechtendal & Chamisso and *P. leiophylla* var. *chihuahuana* Schiede ex Schlechtendal & Chamisso (Engelmann) (Farjon and Styles 1997). Those varieties are considered by others as different species: *P. leiophylla* Schlechtendal & Chamisso and *P. chihuahuana* Engelm. (Martinez 1948; Perry 1991). We decided the lumping after the following considerations:

a) There are not taxonomic consensus about the existence of clearly separate *P. leiophylla* in two varieties, nor their separation in two species (*P. leiophylla* and *P. chihuahuana*). It has being suggested that in Durango, putative *P. leiophylla* var. *leiophylla* has frequently five slender, pendulous needles per fascicle and distribute at higher altitudes and in more moist sites, meanwhile putative *P. leiophylla* var. *chihuahuana* have only three thick spreading needles per fascicle, distributing at lower elevation dryer sites, sympatric to high elevation limits of *P. cembroides* (Farjon and Styles 1997; Flores-López, pers. com. 2012). However, in the southern rank of its distribution both putative varieties merges, to such extent that it becomes very difficult to distinguish them as varieties (Farjon and Styles

¹ Miriam Vargas-Llamas and Rigoberto Palafox-Rivas, pers. com. 21 January 2010, Database Department, National Forest and Soil Inventory, CONAFOR-Guadalajara, México.

1997), even for Martínez (1948) who suggested their separation as species. To add even more taxonomical confusion, populations with the most northern distribution that reaches southern New Mexico and Arizona, although considered *P. chihuahuana* by Perry (1991), it is considered as simply *P. leiophylla* by the USA Inventory data (see Figure 15 on Rehfeldt et al 2006). Finally, analysis of botanical collections and unpublished DNA tests strongly suggests that so far there is not enough evidence to have a definitive classification (Pérez-de-la-Rosa, pers. com.², 2012).

b) The taxonomic confusion is expressed also on the Mexican Forest Inventory data. Although presence observations of *P. leiophylla* var. *leiophylla* and *P. leiophylla* var. *chihuahuana* appears as two different species in the Mexican Forest Inventory data: *P. leiophylla* and *P. chihuahuana*, it turned out that it is because the MexFI does not have a field that allows an entry as variety; thus, CONAFOR itself actually consider those two taxon as *P. leiophylla* varieties and not as different species, based on the classification of Kral (1993), which was validated by the Mexican Commission for the Use and Study of the Biodiversity (CONABIO)³. Also, we plotted altitude presence data of *P. leiophylla* var. *leiophylla* and putative *P. leiophylla* var. *chihuahuana* as recorded as two separate varieties from the Mexican Inventory, against latitude and longitude (Figure 1). The result clearly indicate that observations of both typical and putative variety overlap in altitude and in a large extent in latitude and longitude (overlapping between 1500 m to 2900 m, 22° LN to 31° LN, and 103.5° LW to 109° LW; Figure 1), being putative *P. leiophylla* var. *chihuahuana* with the most northern distribution. Also, there are observations in the MexFI of 71 sites where there is recorded both putative varieties. Overlapping of altitudinal intervals of natural distribution for the two putative varieties or species was also confirmed by botanical observations and field personal observations. The data overlapping in altitude

³ Rebeca Aldana Barajas, Forest Analysis and Information Unit, CONAFOR-Guadalajara, México. 16 October 2012.

is despite the extended view that *P. leiophylla* var. *chihuahuana* occurs at lower altitude and at dryer sites than *P. leiophylla* var. *leiophylla*, at least in the interior slopes of the Sierra Madre Occidental (Flores-López, 2012, pers. com.⁴)

(c) If it were an error to lump together those two putative varieties or species, the error likely will be minor, since they are undoubted phylogenetically closely related (Rodríguez-Banderas et al 2009), sharing unique traits that none other species share, like deciduous fascicle sheaths and (quite unique) three year cone development (Farjon and Styles 1997).

(B)

Figure 1. Elevation (m) of presence observations of *P. leiophylla* var. *leiophylla* (red circles) and putative *P. leiophylla* var. *chihuahuana* (black dots), plotted against Latitude North (A) and latitude plotted against Longitude West (B). Data from the Mexican National Forest and Soil Inventory (updated 2010).

A possible explanation of the overlapping in altitude on the MexFI is that if for taxonomists it is difficult to decide whether those two putative varieties should be kept as such, or as different species, or as the same species, then for CONAFOR field personnel it is even more difficult to distinguish them. So, likely in practice in the field, individuals of both putative varieties are recorded in either way.

Consideration about altitude

After examining the Mexican inventory data, plotting altitude against latitude and longitude (Figure 1), reviewing bibliography available (Martinez 1948; Perry 1991; Farjon and Styles 1997), and discussing the natural elevation observed by botanists and forest taxonomists and geneticist with extensive field and/or botanical collections experience on this specie (personal observations and personal communication with: de-la-Rosa, 2012; Flores-López, 2012; Wehenkel⁵ 2012 and Socoro Gonzalez⁶, 2012), we decided to remove presence plots from the Mexican Inventory data with elevations recorded above 3000 m and below 1500 masl, since likely they are errors either of identification or of entering data. Those likely mistaken observations represented the 2.7 % of the presence data set.

Revised data base of presence

In summary, we lumped together observations of putative varieties of *P. leiophylla* var. *leiophylla* and putative *P. leiophylla* var. *chihuahuana*, and removing likely mistaken observations at altitudes below 1500 m and above 3000 m from the MexFI.

Then, we added 35 observations of *P. leiophylla* from their extreme Northern distribution, at Arizona and Nuevo México. Those populations were collected by Gerald E. Rehfeldt and were used in a climatic modeling of *P. leiophylla* (Rehfeldt et al 2006).

Finally, we added 38 sites from the USA Forest Inventory, from also Arizona and New México, but different than the locations sampled by Rehfeldt et al (2006).

Thus, we ended up with a revised presence data base for *P. leiophylla* of 1475 observations (see attached file Pleio_DataPresence.xlsx and Appendix 1, 2 and 4 for climate values estimated for presence observations).

Sampling of sites with absence

We sampled sites with absence of *P. leiophylla* from a subset of the MexFI data with ca. 14,000 plots with species other than conifers. To assure that our sample of absence observations was representative of the vegetation of Mexico, we also used a systematic sampling of point locations within the digitized map of the Biotic Communities of North America (Brown et al., 1998; Rehfeldt et al 2012). Technical procedures, described in detail in Rehfeldt et al. (2006) and used also by Ledig et al. (2010) involved the use of ARCMAP software to procure a systematic sample of point locations from each polygon on the map and assign an elevation to each point from the digitized elevation model of GLOBE Task Team (1999). Data points from all communities within which *P. leiophylla* can occur (Madrean Montane Conifer Forest, Transvolcanic -Guatemalan Conifer Forests, and Madrean-Transvolcanic Pine-Oak Woodland) were discarded in this step, and some biomes where there are no conifer tree species were explicitly included (Tamaulipan Thornscrub, Gulf Coastal Grassland, Savanna Grasslands, Western Alpine Tundra, California Valley Grassland, California Coastalscrub, Mohave Desertscrub, Pacific Coast Thornscrub, Sonoran Desertscrub, Great Basin Desertscrub, Chihuahuan Desertscrub, Semidesert Grassland and Great Basin Shrub-Grassland).

To assure that the highest and coldest sites in Mexico were represented among the data points that lack *P. leiophylla*, the digitized elevations of GLOBE (1999) were used to obtain a geographic sample of points on the flanks of Mexico's seven tallest volcanic peaks. This procedure produced a data set of 30 observations that, for instance, contained as many as seven data points for Iztaccíhuatl (ca. 19.18°N latitude, 98.64°W longitude) that ranged in elevation from 4291 m to 5142 m.

The procedure provided ca. 145,000 data points, all of which were assumed to lack *P. leiophylla*. The climate of each was estimated from the spline climate surfaces of Saenz-Romero et al. (2010), available at URL <http://forest.moscowfsl.wsu.edu/climate/> . These climate surfaces predict monthly values of temperature and precipitation from which 18 variables of demonstrated importance in plant geography are derived. Additional variables involving the interaction of the 18 derived variables are used herein to produce 34 variables

available for developing bioclimate models. Of the possible interactions, we concentrated on those involving temperature and precipitation.

Bioclimatic model

Our statistical model for predicting the occurrence of climatically suitable habitats of *P. leiophylla* are built on the framework of Iverson and Prasad (1998), Iverson et al (2008) and closely parallel to those of Rehfeldt et al. (2006). The approach uses the Random Forests classification tree (Breiman, 2001), available in R (R Development Core Team, 2004; Liaw and Wiener, 2002), to predict the presence–absence of *P. leiophylla* from climate variables.

For classification trees, Breiman (2001) recommends that the number of observations within classes should be reasonably balanced. We use the sampling protocol of Rehfeldt et al. (2009) to draw from our database 10 datasets. In each dataset, 40% of the observations were those for which *P. leiophylla* was present, weighted by a factor of two (i.e., 2950 observations for each dataset). An additional 40% were drawn from the pool of observations lacking *P. leiophylla* that comprised an 18-variable hypervolume surrounding the climatic limits of *P. leiophylla*. Dimensions of the hypervolume were set at ± 1.25 standard deviations for each variable; the pool consisted of ca. 29,500 observations. The remaining 20% of were selected from a pool of data points lacking *P. leiophylla* and lying outside the hypervolume (pool of approximately 14750 observations). Observations were selected such that a broad range of climate variation was represented: a random sample of ca. 74 observations (1 % of the total) was drawn from each of 10 uniform classes subtending each of the first and second principal components calculated from the 18-variable network for all observations in our database, using the software SAS (SAS 2004). That means: 74 observations x 20 classes = 1480 observations, or about 20% of the total in any one of the 10 data sets.

This sampling procedure thus used all observations with of *P. leiophylla*, concentrated the remainder of the sample in those climates for which separating presence from absence would be the most difficult, but still represented the full range of variation

among the plots. Weighting permitted a higher proportion of the total observations to be used in each forest.

Our analysis was initiated with 10 forests of 100 trees using 34 climate variables to predict the presence of *P. leiophylla*. Each forest used one of our datasets. Variables were eliminated according to a stepwise procedure that culled the least important variable at each step, using the mean decrease in accuracy to judge variable importance (see Breiman and Cutler, 2004). The mean value of this statistic was calculated across the 10 forests at each iteration to determine which variable should be eliminated.

The best model was chosen according to the out-of-bag errors which take into account errors of omission and errors of commission (see Breiman, 2001). When out-of-bag errors began increasing consistently, we assumed that the corresponding model was of reasonable parsimony (see Rehfeldt et al., 2009). This model was used to derive the bioclimate climate model from 10 forests and 100 trees.

Mapping realized contemporary climate niche

Pixels of $\sim 1 \text{ km}^2$ (0.0083 decimal degrees) resolution comprises the terrestrial portion of our geographic window defined as: 33° LN, 13° 54' LN; 117° LW, 86° LW. By using the digitized elevations of GLOBE Task Team (1999), we estimated the climate of each pixel from the spline surfaces of Sáenz-Romero et al. (2010). The climate of each pixel was then run through the bioclimate model using a R program (modules randomForest and yaImpute), with each tree of each forest providing a vote as to whether a pixel fell within the realized climate niche of *P. leiophylla*; a pixel was assumed to have a suitable climate when receiving a majority (> 0.5) of favorable votes.

Pinus pseudostrobus

Considerations about presence data input

We constructed our database of presence observations mainly from field presence observations of *P. pseudostrobus* Lindley, using initially 509 observations from a subset of 6674 observations with presence of conifers from the Mexican National Forest and Soil

Inventory (MexFI), elaborated by the Mexican National Forest Commission (Comisión Nacional Forestal, CONAFOR). Observations were provided from the latest data base version on January 2010, that encompassed field observations from 2004 to 2009 (Vargas-Llamas and Palafox-Rivas, pers. com.⁷, 2012). Mexican Inventory customarily establishes plots with four subplots which were combined for our analysis. We considered *P. pseudostrobus* Lindley as a single species, coded as “*Pinus pseudostrobus*” in the MexFI.

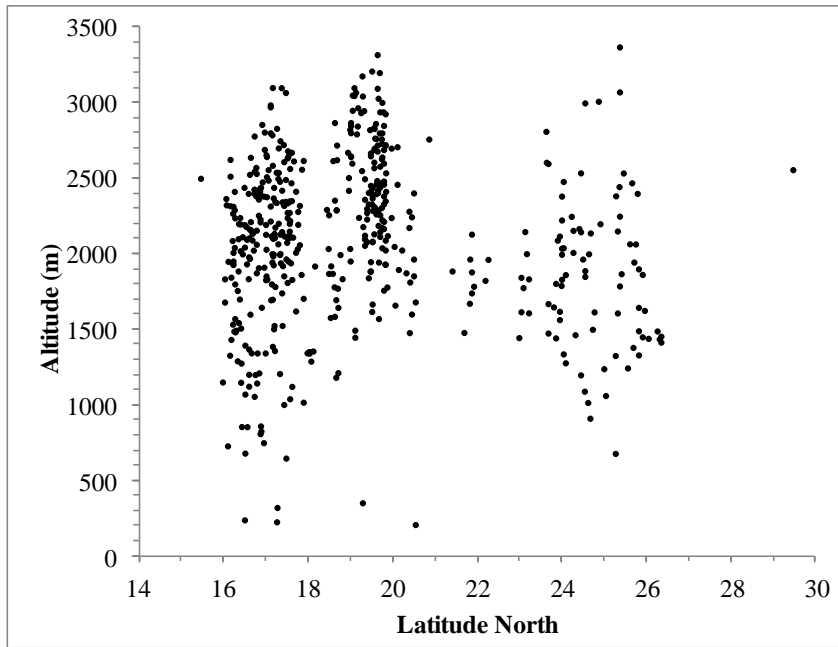

Consideration about latitude and altitude

After examining the Mexican inventory data, plotting altitude against latitude and longitude (Figure 3), reviewing bibliography available (Martinez 1948; Perry 1991; Farjon and Styles 1997), and discussing the natural elevation observed by botanists and forest taxonomists and geneticist with extensive field and/or botanical collections experience on this specie (personal observations), we decided to remove presence plots from the Mexican Inventory data if they were recorded with: (a) elevations below 1600 m if longitude West was lower than 107 °LW, (b) below 1500 m if longitude West was larger or equal than 107 °LN, and (c) latitude North larger than 26 °LN (Northern of Chihuahua state). Those decisions were taken since likely they are errors either of identification or of entering data. Those likely mistaken observations represented the 15.7 % of the initial presence data set.

Thus, the final presence observations accounted for 429 sites (see attached file Ppseu_DataPresence.xlsx and Appendix 1, 3 and 5 for climate values estimated for presence observations).

variables available for developing bioclimate models. Of the possible interactions, we concentrated on those involving temperature and precipitation.

Bioclimatic model

Our statistical model for predicting the occurrence of climatically suitable habitats of *P. pseudostrobus* are built on the framework of Iversen and Prasad (1998), Iversen et al (2008) and closely parallel to those of Rehfeldt et al. (2006). The approach uses the Random Forests classification tree (Breiman, 2001), available in R (R Development Core Team, 2004; Liaw and Wiener, 2002), to predict the presence–absence of *P. pseudostrobus* from climate variables.

For classification trees, Breiman (2001) recommends that the number of observations within classes should be reasonably balanced. We use the sampling protocol of Rehfeldt et al. (2009) to draw from our database 14 datasets. In each dataset, 40% of the observations were those for which *P. pseudostrobus* was present, weighted by a factor of two (i.e., 858 observations for each dataset). An additional 40% were drawn from the pool of observations lacking *P. pseudostrobus* that comprised an 18-variable hypervolume surrounding the climatic limits of *P. pseudostrobus*. Dimensions of the hypervolume were set at ± 1.25 standard deviations for each variable; the pool consisted of ca. 12,000 observations. The remaining 20% were selected from a pool of data points lacking *P. pseudostrobus* and lying outside the hypervolume (pool of ca. 6000 observations). Observations were selected such that a broad range of climate variation was represented in each dataset: a random sample of ca. 21 observations (1 % of the total) was drawn from each of 10 uniform classes subtending each of the first and second principal components calculated from the 18-variable network for all observations in our database, using the software SAS (SAS 2004). That means: 21 observations x 20 classes = 420 observations, or about 20% of the total in any one of the 14 data sets.

This sampling procedure thus used all observations with of *P. pseudostrobus*, concentrated the remainder of the sample in those climates for which separating presence from absence would be the most difficult, but still represented the full range of variation among the plots. Weighting permitted a higher proportion of the total observations to be used in each forest.

Our analysis was initiated with 14 forests of 100 trees using 34 climate variables to predict the presence of *P. pseudostrabus*. Each forest used one of our datasets. Variables were eliminated according to a stepwise procedure that culled the least important variable at each step, using the mean decrease in accuracy to judge variable importance (see Breiman and Cutler, 2004). The mean value of this statistic was calculated across the 14 forests at each iteration to determine which variable should be eliminated.

The best model was chosen according to the out-of-bag errors which take into account errors of omission and errors of commission (see Breiman, 2001). When out-of-bag errors began increasing consistently, we assumed that the corresponding model was of reasonable parsimony (see Rehfeldt et al., 2009). This model was used to derive the bioclimate climate model from 14 forests and 100 trees.

Mapping realized contemporary climate niche

Pixels of $\sim 1 \text{ km}^2$ (0.0083 decimal degrees) resolution comprises the terrestrial portion of our geographic window defined as: 33° LN, 13° 54' LN; 117° LW, 86° LW. By using the digitized elevations of GLOBE Task Team (1999), we estimated the climate of each pixel from the spline surfaces of Sáenz-Romero et al. (2010). The climate of each pixel was then run through the bioclimate model using a R program (modules randomForest and yaImpute), with each tree of each forest providing a vote as to whether a pixel fell within the realized climate niche of *P. pseudostrabus*; a pixel was assumed to have a suitable climate when receiving a majority (> 0.5) of favorable votes.

Results

Pinus leiophylla

Bioclimate model

The 34-variable model produced a classification error that averaged 4.61 % across the 10 ‘forests’. As variables were eliminated in the stepwise procedure, this error fluctuated between 4.52 % (for 31 variables in the model) and 5.23 % (for 3 variables in the model). Errors for the 2-variable model increased to 6.10 % and to 20.12 % for one-variable model. The lowest error with a small number of variables was for the 6-variable model which, when run anew to produce the bioclimate model, had an error of 4.63 %, with errors caused by predicting *P. leiophylla* to be present when absent averaging 7.20 % while those caused from predicting *P. leiophylla* to be absent when present were nill (0.79 %). The six climatic variables, listed in order of importance, were: SUMP, GSDD5, SPRP, MTCMMAP, WINP, and MAPDD5 (Table 1).

.....

Table 1. Acronyms, derivation, and ranking of climatic variables of greatest relevance to the climate profile of *Pinus leiophylla*.

Acronym	Definition	Importance ranking
MAT	Mean annual temperature (°C)	-
MAP	Mean annual precipitation (mm)	-
DD5	Degree-days > 5°C	-
ADI	Annual Dryness Index: $(DD5^{0.5})/MAP$	-
GSP	April-September precipitation	-
GSDD5	Degree-days > 5°C summed between the last freeze of spring and the first freeze of autumn; that is, between SDAY and FDAY	-
MTCM	Mean temperature of the coldest month	-
SDAY	Julian date of the last freezing date of Spring	-

FDAY	Julian date of the first freezing date of Autumn	-
SUMP	Summer precipitation: Sum of precipitation of July and August	1
GSDD5	Degree-days > 5°C summed between the last freeze of spring and the first freeze of autumn; that is, between SDAY and FDAY	2
SPRP	Spring precipitation: Sum of precipitation of April and May	3
MTCMMAP	MTCM/MAP	4
WINP	Winter precipitation: Sum of precipitation of November, December, January and February	5
MAPDD5	(MAP*DD5)/1000	6

As measured by the overall classification error, the fit of our bioclimate model using 6 predictors is among the intermediate of those for 74 western USA species for which the same methods have been used (Crookston et al., 2010). For the latter group, classification errors ranged from 1.4 % to 11.0 %. For conifers of Mexico, errors were 4.5 % for *Picea* spp. (Ledig et al., 2010) and 4.7 % for *Pinus chiapensis* (Sáenz-Romero et al., 2010).

In bioclimate modeling, the most serious errors are in predicting the absence of a species when it was present, that is, the errors of omission. While many ecologically sound reasons may prevent a species from occurring in climates for which it is well suited, the most likely source of the errors of omission are in the model fitting process (see, for instance, Rehfeldt et al. 2009). In our analyses, like those of many western USA species (see Crookston et al., 2010), errors of omission were essentially nonexistent, a result directly linked to the sampling protocol which weights by a factor of two those observations in which the species of interest was present (see Rehfeldt et al., 2009).

Mapped contemporary climate profile

The precision of the bioclimate model is further apparent by superimposing the locations inhabited by *P. leiophylla* on climate profile (Fig. 2). Nearly all data points occur

in grid cells for which the likelihood was high that the climate would be suited for the species.

The area where the climate is predicted to be suitable for *P. leiophylla* is greater than the actual distribution. This result is to be expected when habitat suitability is predicted on the basis of climate alone. Many other factors may restrict where a species actually occurs, e.g., substrate, interactions with other species, or restrictions on seed dispersal (see Pearson and Dawson, 2003 ; van Zonneveld et al., 2009). In addition, using the majority of votes (> 0.5) to predict presence or absence prevents identification of locations where the climate may approach suitability (for example, with: $0.25 < \text{votes} < 0.50$). Nonetheless, a portion of the classification error results from correctly predicting suitable niche space that is, by chance, not occupied.

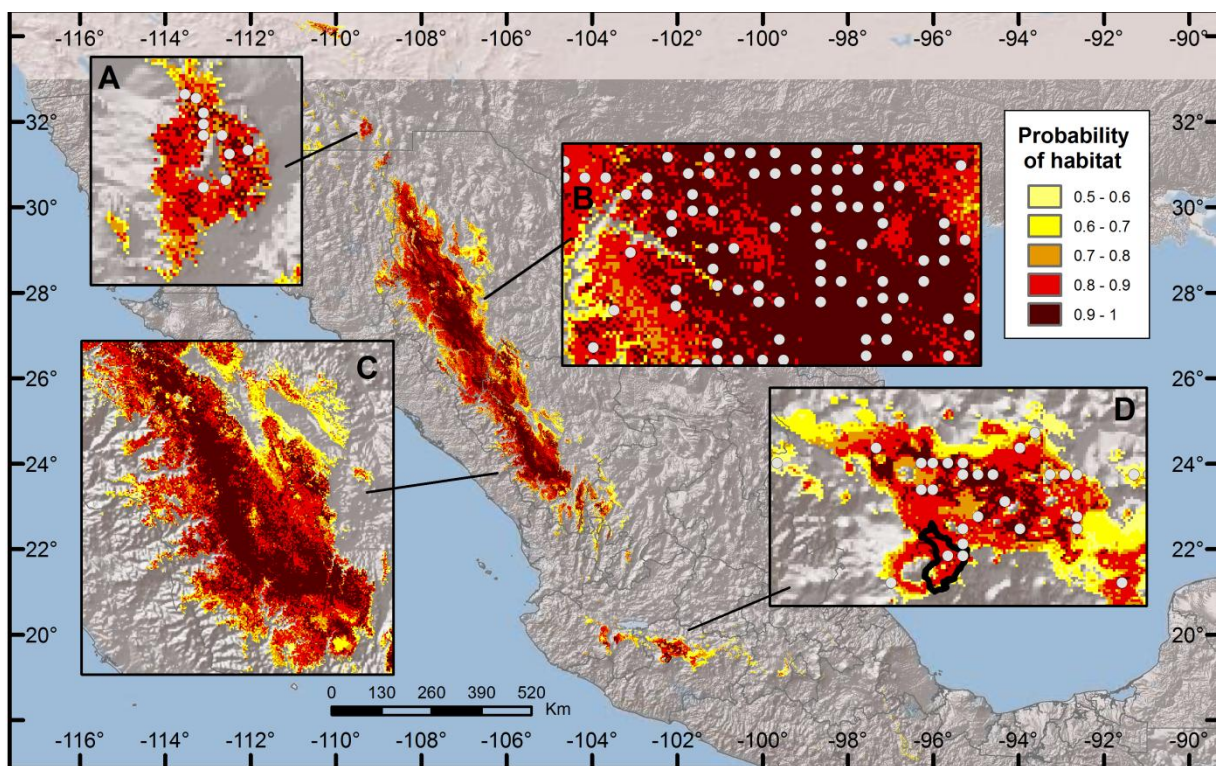

Figure 2. Mapped locations of areas predicted by the bioclimate model to lie within the contemporary climate niche of *Pinus leiophylla*. Shades (yellow to dark brown) show the likelihood (from 0.5 to 1.0) that the climate is suitable. Symbols (gray circles) locate existing populations as recorded by the Mexican forest inventory. Panels show distribution areas in Chiricahua mountains, Arizona, USA (A), interior slopes of Sierra Madre Occidental at southern Chihuahua state (B) and southern Durango state (C, Mexican forest

inventory presence sites not indicate), and Pico de Tancítaro National Park and forest of the Native Indian Community of Nuevo San Juan Parangaricutiro (black contour), Michoacán state (D).

Predicted distribution of the suitable climatic habitat well represents the actual distribution mainly along the interior slopes of the Sierra Madre Occidental (Figure 2B, C), along an area of transition between the high altitude colder and moister conifer and pine-oak forest of the Sierra Madre Occidental and the warmer and dryer pinyon-pine forest at the lower part of the slopes of the Sierra. The extreme northern distribution that reaches Arizona, USA, is well represented at the Chiricahua mountains (Figure 2A). On the Trans-Mexican Volcanic Belt, their predicted distribution appears with lower probability of occurrence (mostly between 0.5 and 0.8; Figure 2D), which is congruent with our direct observation that in that area, *P. leiophylla* in general does not conform pure stands; almost allways is in mixed stands. The prediction in general is in agreement of maps developed by Perry (1991), Farjon and Styles (1997) and Rodríguez-Banderas et al (2009).

The extent of predicted distribution area (probability > 0.5) for the specie in México and in USA is show in Table 2.

Table 2. Predicted area of suitable climatic habitat (thousands of km²) for *Pinus leiophylla* per country and per interval of probability.

Country	Probability of suitable		Total Country
	climatic habitat		
	0.5 to 0.8	0.8 to 1	
México	70.0	107.9	177.9
USA	4.8	1.9	6.7
Total species	74.8	109.8	184.6

Pinus pseudostrabus

Bioclimate model

The 34-variable model produced a classification error that averaged 6.45 % across the 14 ‘forests’. As variables were eliminated in the stepwise procedure, this error fluctuated between 5.84 % (for 31 variables in the model) and 6.96 % (for 3 variables in the model). Errors for the 2-variable model increased to 10.55 % and to 20.46 % for one-variable model. The lowest error with a small number of variables was for the 7-variable model which, when run anew to produce the bioclimate model, had an error of 5.70 %, with errors caused by predicting *P. pseudostrabus* to be present when absent averaging 9.26 % while those caused from predicting *P. pseudostrabus* to be absent when present were nill (0.36 %). The seven climatic variables, listed in order of importance, were: MMAX, SPRP, MTCMMAP, MMIN, WINP, MAPMTCM and SUMP (Table 3).

.....

Table 3. Acronyms, derivation, and ranking of climatic variables of greatest relevance to the climate profile of *Pinus pseudostrabus*.

Acronym	Definition	Importance ranking
MAT	Mean annual temperature (°C)	-
MAP	Mean annual precipitation (mm)	-
DD5	Degree-days > 5°C	-
ADI	Annual Dryness Index: $(DD5^{0.5})/MAP$	-
MTCM	Mean temperature of the coldest month	-
MMAX	Mean maximum temperature in the warmest month	1
SPRP	Spring precipitation: Sum of precipitation of April and May	2
MTCMMAP	MTCM/MAP	3
MMIN	Mean minimum temperature in the coldest month	4
WINP	Winter precipitation: Sum of precipitation of November, December, January and February	5

MAPMTCM	(MAP * MTCM)/1000	6
SUMP	Summer precipitation: Sum of precipitation of July and August	7

Similar to the modeling of *P. leiophylla*, the errors of omission were essentially nonexistent, a result directly linked to the sampling protocol which weights by a factor of two those observations in which the species of interest was present (see Rehfeldt et al., 2009).

Mapped contemporary climate profile

The precision of the bioclimate model is further apparent by superimposing the locations inhabited by *P. pseudostrobus* on climate profile (Fig. 4). Nearly all data points occur in grid cells for which the likelihood was high (> 0.5) that the climate would be suited for the species.

The area where the climate is predicted to be suitable for *P. pseudostrobus* is greater than the actual distribution. This result is to be expected when habitat suitability is predicted on the basis of climate alone. Many other factors may restrict where a species actually occurs, e.g., substrate, interactions with other species, or restrictions on seed dispersal (see Pearson and Dawson, 2003 ; van Zonneveld et al., 2009). In addition, using the majority of votes (> 0.5) to predict presence or absence prevents identification of locations where the climate may approach suitability (for example, with: 0.25 <votes < 0.50) . Nonetheless, a portion of the classification error results from correctly predicting suitable niche space that is, by chance, not occupied.

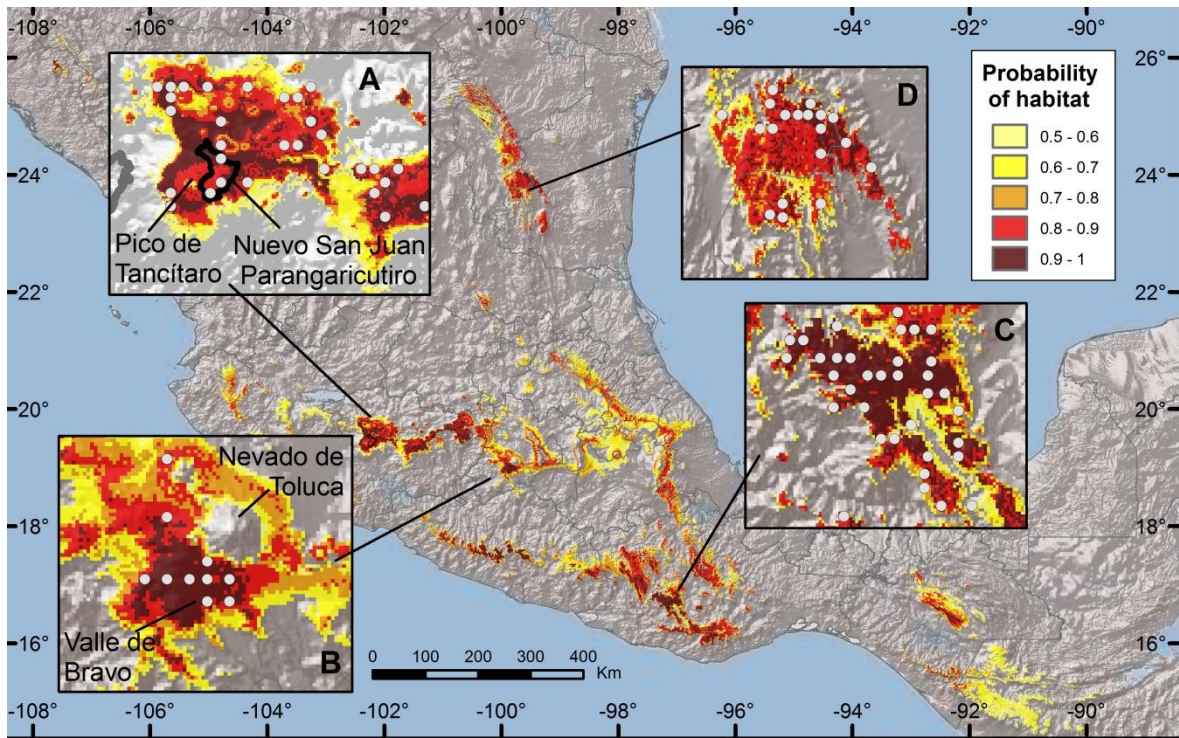

Figure 4. Mapped locations of areas predicted by the bioclimate model to lie within the contemporary climate niche of *Pinus pseudostrobus*. Shades (yellow to dark brown) show the likelihood (from 0.5 to 1.0) that the climate is suitable. Symbols (gray circles) locate existing populations as recorded by the Mexican forest inventory. Panels show distribution areas at Pico de Tancitaro National Park and forest of the Native Indian Community of Nuevo San Juan Parangaricutiro (black contour), Michoacán state (A), slopes near of Nevado de Toluca volcano, state of México (B), near of Santa María and San Vicente Lachixío, central-southern Oaxaca state (C), and slopes of Sierra Madre Oriental at the border of Nuevo León and Tamaulipas states (D).

Predicted distribution of the suitable climatic habitat well represent the actual distribution, mainly along narrow strips at the the Trans-Mexican Volcanic Belt, with important areas of distribution as pure stands in moist and cold or temperate sites at the slopes of high elevation mountains, like Pico de Tancitaro, Michoacán (including the forest of the Native Indian community of Nuevo San Juan Parangaricutiro, Figure 4A) or Nevado de Toluca volcano, near of Valle de Bravo, México state (Figure 2B). There is also important distribution along moist and temperate or colder slopes of Sierra Madre Oriental, at the Reserva de la Biósfera El Cielo at Tamaulipas and northern of that Resertve (Figure

4D, as well as moist slopes of Sierra Madre Oriental along the Sierra Norte de Puebla and Sierra Norte de Oaxaca (Figure 2). There are an important distribution area around the communities of Santa María and San Vicente Lachixío, central-southern Oaxaca state (Figure 4C). The extreme south-eastern distribution that reaches the highlands of Los Altos de Chiapas state and Guatemala is also well represented (bottom-right of Figure 4). The prediction in general is in agreement of maps developed by Perry (1991) and Farjon and Styles (1997).

The extent of predicted distribution area (probability > 0.5) for the specie in México and in Guatemala is show in Table 4.

Table 4. Predicted area of suitable climatic habitat (thousands of km²) for *Pinus pseudostrobus* per country and per interval of probability.

Country	Probability of suitable		
	climatic habitat		Total Country
	0.5 to 0.8	0.8 to 1	0.5 to 1
México	63.3	40.3	103.6
Guatemala	10.9	0.1	11.0
Total species	74.2	40.4	114.6

Considerations and cravats

Although we found some putative mistakes in the Mexican National Forest and Soil Inventory (MexFI), specially related to altitudes too high or too low (we guess due to deficiency of calibration of equipment, errors in data entry and errors in taxonomic identification, perhaps in that order of importance), the large amount of field observation of presence included in the MexFI, makes that data base a powerful tool to conduct climatic habitat distribution modeling.

The possible taxonomic identity confusions in the MexFI, like *P. leiophylla* var. *leiophylla* vs. *P. leiophylla* var. *chihuahuana* \approx *P. chihuahuana* (discussed in the Methodology section, Considerations about presence data input subsection) is an issue that it is not realistic that will be solved by field personnel that that visited the field plots for the MexFI. If there is no consensus about taxonomic identity in the specialized literature and among the most experienced botanist, how could we expect that field work teams could not have confusions?

Presence observations derived from herbarium collection can complement but not replace the MexFI data base as data source for this type of modeling. In our experience, herbarium collections have the same type of errors than the MexFI: confusion or errors in taxonomic determination, elevation and geographic coordinates with errors due to deficiency of calibration of equipment or data entry, etc.

The most difficult part of the modeling was to construct an absence data set reasonable and equilibrated, where 40% of the observations were drawn from the pool of observations lacking the specie of interest, surrounding the climatic limits of the species of interest, considering that the number of absence data is nearly infinite in comparison with the presence data.

We consider a progress in the climatic data the availability of precipitation for specific periods of the year (like SPRP = Spring precipitation = Sum of precipitation of April and May), and its respective ratios, something new in comparison to previous versions of the spline climatic models available at <http://forest.moscowfsl.wsu.edu/climate/>.

Conclusions

The suitable climatic habitat for *Pinus leiophylla* was predicted for approximately 178,000 km² on Méxican territory and 6,700 km² on USA territory, with a probability of presence > 0.5, an average error of 4.6 %, and under the contemporary climate (average of the period 1961 – 1990). Its main distribution is along the interior slopes of Sierra Madre Occidental and less along the western portion of the Trans-Mexican Volcanic Belt, with an

extreme northward small fragmented distribution at the Chiricahua mountains, Arizona, USA.

The suitable climatic habitat for *Pinus pseudostrabus* was predicted for approximately 103,600 km² on Mexican territory and 11,000 km² on Guatemalan territory, with a probability of presence > 0.5, an average error of 5.7 %, and under the contemporary climate (average of the period 1961 – 1990). Its main distribution is along the Trans-Mexican Volcanic Belt, the Sierra Madre Oriental, the Sierra Madre del Sur, Los Altos de Chiapas and at the highlands of Guatemala, in that approximate order of importance.

Appendix 3

Mean, minimum, maximum and standard deviation of altitude (m) and of climatic values for 429 sites with presence of *Pinus pseudostrabus*. Presence data is from Mexican Forest Inventory data (Mexican National Forest Commission) and climatic data was estimated from a spline climatic model (Sáenz-Romero et al 2010; Crookston and Rehfeldt 2011). Climatic variable keys as on Appendix 1.

Appendix 4

Coordinates, altitude and climatic values for 1475 sites with presence of *Pinus leiophylla*. Presence data is from Mexican Forest Inventory data (Mexican National Forest Commission) and climatic data was estimated from a spline climatic model (Sáenz-Romero et al 2010; Crookstone and Rehfeldt 2011). Climatic variable keys as on Appendix 1. Units are indicated after the variable key.

Appendix 5

Coordinates, altitude (m) and climatic values for 429 sites with presence of *Pinus pseudostrabus*. Presence data is from Mexican Forest Inventory data (Mexican National Forest Commission) and climatic data was estimated from a spline climatic model (Sáenz-Romero et al 2010; Crookstone and Rehfeldt 2011). Climatic variable keys as on Appendix 1. Units are indicated after the variable key.
